Green Computing-E-Waste Minimization

Vaishali Sindekar

Assistant Professor, Dept. of Computer Science, Sonopant Dandekar College, Palghar

Yugandhara More

Assistant Prof., Department of Computer Science, Sonopant Dandekar College, Palghar.

Abstract:

Green computing is the study and practice of using computing resources efficiently and eco-friendly. The goals are that is to reduce the use of hazardous materials, maximize energy efficiency during the product's lifetime, and promote recyclability or biodegradability of defunct products and factory waste. In recent years, companies in the computer industry have come to realize that going green is in their best interest, both in terms of public relations and reduced costs. This paper presents at several green initiatives currently under way in the computer industry, as well as issues that have been raised regarding these initiatives and presents a study about the green computing. Ultimately green computing focuses on ways in reducing overall environmental impact, its main purpose is to find and promote new ways of reducing pollution, discovering alternative technologies, and creating more recyclable products.

Keywords: E-waste, Environment, Green Computing, Eco-Friendly

Introduction:

Green computing, or green IT, will improve the way computing devices are not only being used but the devices IT uses and how their infrastructure is designed. Businesses are "going green" in many areas, but specifically in IT because data centers and servers are the biggest offenders when it comes to IT inefficiency. We may have even heard the buzz around "green computing."

Many organizations today have an abundance of servers, and most of them are underutilized. Typically servers operate at 5%-20% of full processing capacity, but are still

using energy. Tack on the cost it takes to run hundreds if not thousands of desktop PCs everyday and power costs alone are putting dents in already tight IT budgets everywhere.

E-waste:

"E-waste" is a popular, informal name for electronic products nearing the end of their "useful life." E-wastes are considered dangerous, as certain components of some electronic products contain materials that are hazardous, depending on their condition and density. The hazardous content of these materials pose a threat to human health and environment. Discarded computers, televisions, VCRs, stereos, copiers, fax machines, electric lamps, cell phones, audio equipment and batteries if improperly disposed can leach lead and other substances into soil and groundwater.

E-WASTE

**Alkaline batteries:
toxic landfill after one use**

Benefits of a Green IT Environment:

➤ Reducing Environmental Impact:

- Thin clients consume an average of 8-20 watts compared to an average of 150 watt per PC.
- Thin clients significantly lower a company's environmental footprint by reducing energy consumption and CO₂ emissions during use.

➤ Financial Savings:

- Cost savings from electricity can be reinvested.
- Thin client computing also lowers operating and administration costs.

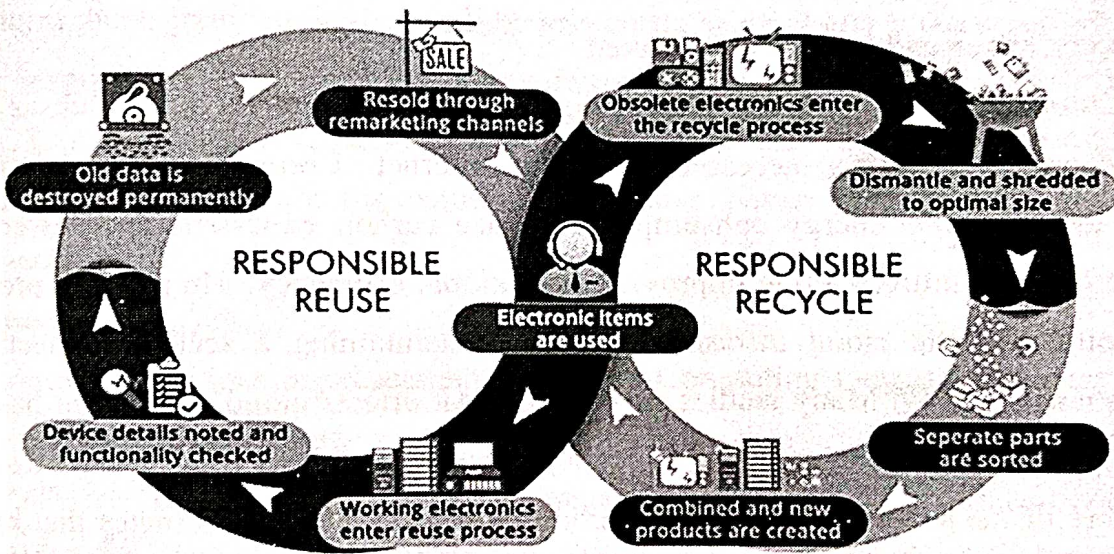

➤ **Recycling:**

- Because thin clients have a longer life span and are built in a significantly smaller form factor, they last longer and can be recycled.
- Thin Clients are RoHS(Restriction of Hazardous Substances) compliant. They meet the regulation regarding the restriction of the use of certain hazardous substances in electrical and electronic equipment.

More and more businesses are adopting green computing solutions for their IT environment. Switching to thin clients from PCs is one of the simplest and most effective ways to work towards a greener IT. Thin client provide a similar user experience but consume only a fraction of the energy required to run individual desktops.

E-Waste Minimization:

E-WASTE MANAGEMENT

1. Shutdown and Turn Off- Reduce the amount of power used by a computer when it is not in use. This is easy to do but is often overlooked, but if done correctly it can amount to huge savings. Roughly one third of the electrical usage of an entire computer comes from the monitor. Use energy saving modes such as sleep, standby, or hibernate, to reduce the amount of power while away from the computer. Turn off the screensaver; it uses just as much energy as if the monitor were in use while using energy-saving modes reduces some power, it is better to turn off the monitor and shutdown the computer to completely eliminate

power usage. It is also important to switch the power off at the wall socket or unplug the device. A computer left on overnight for a year creates enough CO₂ to fill a double-decker bus. Look for software that can help facilitate energy savings such as the Echo™ Thin Client Management Software that allows the administrator to program thin clients to shut down rather than go into "sleep" mode.

2. Virtualization- Virtualization includes separating the physical location of a thin or zero client devices from its logical interface. As applied to data centers, installing virtual infrastructure consolidates servers onto fewer pieces of hardware. It reduces overall energy use and cooling requirements and provides more computing power in less space. Thin clients consume an average of 8-20 watts compared to a 150 watt PC. With these measures, energy consumption can decrease by 80%. Every server that is virtualized saves 7,000 kWh of electricity and 4 tons of carbon dioxide emissions per year. Virtualization also increases IT capacity, improving server utilization rates from 5-15% to 60-80%. By running fewer, highly utilized servers, space and power can be saved.

3. Cloud computing- Cloud computing is where different services—such as servers, storage and applications—are accessed over the Internet. Companies that adopt cloud computing can decrease energy consumption, reduce carbon emissions and lower capital expenditure on IT resources while improving operational efficiency. Thin clients provide an entrance point into the cloud infrastructure while maintaining a secure connection and increasing manageability. Many studies reveal the great effects cloud computing has on the environment such as limiting resource allocation requirements, requiring less hardware and utilizing more of the server's power. The Carbon Disclosure Project estimates that by 2020, large US companies using cloud computing can achieve annual energy savings of \$12.3 billion. A study conducted by Microsoft shows that companies that adopt cloud computing rather than running their own applications, can reduce energy use and carbon footprint of computing by up to 90% for smaller less efficient companies, and by 30% for large already efficient companies.

4. Reuse, Repurpose, Recycle- Computers are made from valuable resources and materials that require a lot of energy to mine and manufacture. In fact, the amount of fossil fuels and chemicals required in the manufacture of one desktop computer is over 9 times the weight of the computer. According to PC Stats, the average useful (capable of running

contemporary software) lifespan of a computer is 5 years. However, the Western Sustainability and Pollution Network (WSPPN) estimates that on average, Americans dispose their PC after only 30 months of use. Before deciding to discard a computer, make sure to consider all options. One alternative to buying a new computer is upgrading the hardware or software of the current computer or repurposing the current computer. Software such as VDI Blaster™, can provide a simple solution to transform a PC into a thin client, extending the capital investment of PCs. In the event a computer must be disposed, donate or recycle the computer to help conserve natural resources. Recycling one million laptops saves the energy equivalent to the electricity used by more than 3,500 US homes in a year.

Conclusion:

Green computing minimizes the energy consumption of the organization i.e. minimizes the power bill. Use of non-toxic material in the equipments makes the worker safe from health problem and occupational hazards. It saves the resource of the country as a whole. In the long term these green equipment will be less costly without any hidden cost of waste and enhanced resource consumption without any detrimental effect of accuracy, performance and longevity. It is therefore concluded that appropriate legislation / regulations, user education & awareness and recycling are the solutions to reduce power consumption and minimize environmental waste.
